Probabilistic classification - generative models

Corso di Laurea Magistrale in Informatica

Università di Roma Tor Vergata

Prof. Giorgio Gambosi

a.a. 2021-2022

Naive Bayes classifiers recap

A language model is a (categorical) probability distribution on a vocabulary of terms (possibly, all words which occur in a large collection of documents).

Use

A language model can be applied to predict (generate) the next term occurring in a text. The probability of occurrence of a term is related to its information content and is at the basis of a number of information retrieval techniques.

Hypothesis

It is assumed that the probability of occurrence of a term is independent from the preceding terms in a text (bag of words model).

a.a. 2021-2022 2/3

Bayesian classifiers

A language model can be applied to derive document classifiers into two or more classes through Bayes' rule.

- \odot given two classes C_1 , C_2 , assume that, for any document d, the probabilities $p(C_1|d)$ and $p(C_2|d)$ are known: then, d can be assigned to the class with higher probability
- ⊚ how to derive $p(C_k|d)$ for any document, given a collection \mathscr{C}_1 of documents known to belong to C_1 and a similar collection \mathscr{C}_2 for C_2 ? Apply Bayes' rule:

$$p(C_k|d) \propto p(d|C_k)p(C_k)$$

the evidence p(d) is the same for both classes, and can be ignored.

 \odot we have still the problem of computing $p(C_k)$ and $p(d|C_k)$ from \mathscr{C}_1 and \mathscr{C}_2

a.a. 2021-2022 3/3:

Bayesian classifiers

Computing $p(C_k)$

The prior probabilities $p(C_k)$ (k=1,2) can be easily estimated from $\mathcal{C}_1,\mathcal{C}_2$: for example, by applying ML, we obtain

$$p(C_k) = \frac{|\mathcal{C}_1|}{|\mathcal{C}_1| + |\mathcal{C}_2|}$$

a.a. 2021-2022 4/32

Naive bayes classifiers

Computing $p(d|C_k)$

For what concerns the likelihoods $p(d|C_k)$ (k = 1, 2), we observe that d can be seen, according to the bag of words assumption, as a multiset of n_d terms

$$d=\{\bar{t}_1,\bar{t}_2,\dots,\bar{t}_{n_d}\}$$

By applying the product rule, it results

$$\begin{split} p(d|C_k) &= p(\overline{t}_1, \dots, \overline{t}_{n_d}|C_k) \\ &= p(\overline{t}_1|C_k)p(\overline{t}_2|\overline{t}_1, C_k) \cdots p(\overline{t}_{n_d}|\overline{t}_1, \dots, \overline{t}_{n_d-1}, C_k) \end{split}$$

a.a. 2021-2022 5/3

Naive bayes classifiers

The naive Bayes assumption

Computing $p(d|C_k)$ is much easier if we assume that terms are pairwise conditionally independent, given the class C_k , that is, for $i, j = 1, ..., n_d$ and k = 1, 2,

$$p(\bar{t}_i, \bar{t}_j | C_k) = p(\bar{t}_i | C_k) p(\bar{t}_2 | C_k)$$

as, a consequence,

$$p(d|C_k) = \prod_{j=1}^{n_d} p(\bar{t}_j|C_k)$$

that is, we model the document as a set of samples from a categorical distribution (the language model): ML is applied to select the best categorical distribution (class)

Language models and NB classifiers

The categorical distributions $p(\bar{t}_j|C_k)$ have been derived for C_1 and C_2 , respectively from documents in \mathscr{C}_1 and \mathscr{C}_2 .

a.a. 2021-2022 6/3

Generative models

- © Classes are modeled by suitable conditional distributions $p(\mathbf{x}|C_k)$ (language models in the previous case): it is possible to sample from such distributions to generate random documents statistically equivalent to the documents in the collection used to derive the model.
- \odot Bayes' rule allows to derive $p(C_k|\mathbf{x})$ given such models (and the prior distributions $p(C_k)$ of classes)
- \odot We may derive the parameters of $p(\mathbf{x}|C_k)$ and $p(C_k)$ from the dataset, for example through maximum likelihood estimation
- \odot Classification is performed by comparing $p(C_k|\mathbf{x})$ for all classes

a.a. 2021-2022 7/32

Deriving posterior probabilities

Let us consider the binary classification case and observe that

$$p(C_1|\mathbf{x}) = \frac{p(\mathbf{x}|C_1)p(C_1)}{p(\mathbf{x}|C_1)p(C_1) + p(\mathbf{x}|C_2)p(C_2)} = \frac{1}{1 + \frac{p(\mathbf{x}|C_2)p(C_2)}{p(\mathbf{x}|C_1)p(C_1)}}$$

Let us define

$$a = \log \frac{p(\mathbf{x}|C_1)p(C_1)}{p(\mathbf{x}|C_2)p(C_2)} = \log \frac{p(C_1|\mathbf{x})}{p(C_2|\mathbf{x})}$$

that is, *a* is the log of the ratio between the posterior probabilities (log odds)

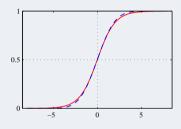

We obtain that

$$p(C_1|\mathbf{x}) = \frac{1}{1+e^{-a}} = \sigma(a)$$
 $p(C_2|\mathbf{x}) = 1 - \frac{1}{1+e^{-a}} = \frac{1}{1+e^a}$

 \circ $\sigma(x)$ is the logistic function or (sigmoid)

a.a. 2021-2022 8/32

Sigmoid

Useful properties of the sigmoid

$$\circ$$
 $\sigma(-x) = 1 - \sigma(x)$

a.a. 2021-2022 9 / 32

Deriving posterior probabilities

 \odot In the case K > 2, the general formula holds

$$p(C_k|\mathbf{x}) = \frac{p(\mathbf{x}|C_k)p(C_k)}{\sum_j p(\mathbf{x}|C_j)p(C_j)}$$

 \odot Let us define, for each k = 1, ..., K

$$a_k(\mathbf{x}) = \log(p(\mathbf{x}|C_k)p(C_k)) = \log p(\mathbf{x}|C_k) + \log p(C_k)$$

Then, we may write

$$p(C_k|\mathbf{x}) = \frac{e^{a_k}}{\sum_j e^{a_j}} = s(a_k)$$

- \circ s(x) is the softmax function (or normalized exponential) and it can be seen as an extension of the sigmoid to the case K > 2
- ⊚ $s(\mathbf{x})$ can be seen as a smoothed version of the maximum: if $a_k \gg a_j$ for all $j \neq k$, then $s(a_k) \simeq 1$ and $s(a_j) \simeq 0$ for all $j \neq k$

a.a. 2021-2022 10/32

Gaussian discriminant analysis

In Gaussian discriminant analysis (GDA) all class conditional distributions $p(\mathbf{x}|C_k)$ are assumed gaussians. This implies that the corresponding posterior distributions $p(C_k|\mathbf{x})$ can be easily derived.

Hypothesis

All distributions $p(\mathbf{x}|C_k)$ have same covariance matrix Σ , of size $D \times D$. Then,

$$p(\mathbf{x}|C_k) = \frac{1}{(2\pi)^{d/2}|\Sigma|^{1/2}} exp\left(-\frac{1}{2}(\mathbf{x} - \boldsymbol{\mu}_k)^T \Sigma^{-1}(\mathbf{x} - \boldsymbol{\mu}_k)\right)$$

a.a. 2021-2022 11/32

Binary case

If
$$K=2$$
,

$$p(C_1|\mathbf{x}) = \sigma(a(\mathbf{x}))$$

where

$$\begin{split} a(\mathbf{x}) &= \log \frac{p(\mathbf{x}|C_1)p(C_1)}{p(\mathbf{x}|C_2)p(C_2)} \\ &= \log \frac{\frac{1}{(2\pi)^{d/2}|\Sigma|^{1/2}}exp\left(-\frac{1}{2}(\mathbf{x} - \boldsymbol{\mu}_1)^T\Sigma^{-1}(\mathbf{x} - \boldsymbol{\mu}_1)\right)p(C_1)}{\frac{1}{(2\pi)^{d/2}|\Sigma|^{1/2}}exp\left(-\frac{1}{2}(\mathbf{x} - \boldsymbol{\mu}_2)^T\Sigma^{-1}(\mathbf{x} - \boldsymbol{\mu}_2)\right)p(C_2)} \\ &= \frac{1}{2}(\boldsymbol{\mu}_2^T\Sigma^{-1}\boldsymbol{\mu}_2 - \mathbf{x}^T\Sigma^{-1}\boldsymbol{\mu}_2 - \boldsymbol{\mu}_2^T\Sigma^{-1}\mathbf{x}) - \\ &- \frac{1}{2}(\boldsymbol{\mu}_1^T\Sigma^{-1}\boldsymbol{\mu}_1 - \mathbf{x}^T\Sigma^{-1}\boldsymbol{\mu}_1 - \boldsymbol{\mu}_1^T\Sigma^{-1}\mathbf{x}) + \log \frac{p(C_1)}{p(C_2)} \end{split}$$

12 / 32

Binary case

Observe that the results of all products involving Σ^{-1} are scalar, hence, in particular

$$\mathbf{x}^T \Sigma^{-1} \boldsymbol{\mu}_1 = \boldsymbol{\mu}_1^T \Sigma^{-1} \mathbf{x}$$
$$\mathbf{x}^T \Sigma^{-1} \boldsymbol{\mu}_2 = \boldsymbol{\mu}_2^T \Sigma^{-1} \mathbf{x}$$

Then,

$$a(\mathbf{x}) = \frac{1}{2} (\boldsymbol{\mu}_2^T \Sigma^{-1} \boldsymbol{\mu}_2 - \boldsymbol{\mu}_1^T \Sigma^{-1} \boldsymbol{\mu}_1) + (\boldsymbol{\mu}_1^T \Sigma^{-1} - \boldsymbol{\mu}_2^T \Sigma^{-1}) \mathbf{x} + \log \frac{p(C_1)}{p(C_2)} = \mathbf{w}^T \mathbf{x} + w_0$$

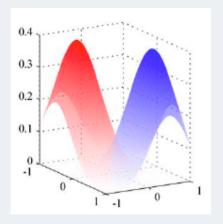

with

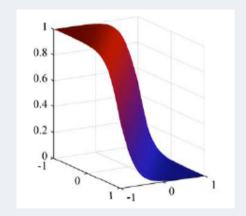

$$\mathbf{w} = \Sigma^{-1}(\boldsymbol{\mu}_1 - \boldsymbol{\mu}_2)$$

$$w_0 = \frac{1}{2}(\boldsymbol{\mu}_2^T \Sigma^{-1} \boldsymbol{\mu}_2 - \boldsymbol{\mu}_1^T \Sigma^{-1} \boldsymbol{\mu}_1) + \log \frac{p(C_1)}{p(C_2)}$$

 $p(C_1|\mathbf{x}) = \sigma(\mathbf{w}^T\mathbf{x} + w_0)$ is computed by applying a non-linear function to a linear combination of the features (generalized linear model)

a.a. 2021-2022 13/32

Left, the class conditional distributions $p(\mathbf{x}|C_1)$, $p(\mathbf{x}|C_2)$, gaussians with D=2. Right the posterior distribution of C_1 , $p(C_1|\mathbf{x})$ with sigmoidal slope.

a.a. 2021-2022 14/32

Discriminant function

The discriminant function can be obtained by the condition $p(C_1|\mathbf{x}) = p(C_2|\mathbf{x})$, that is, $\sigma(a(\mathbf{x})) = \sigma(-a(\mathbf{x}))$.

This is equivalent to $a(\mathbf{x}) = -a(\mathbf{x})$ and to $a(\mathbf{x}) = 0$. As a consequence, it results

$$\mathbf{w}^T\mathbf{x} + w_0 = 0$$

or

$$\Sigma^{-1}(\boldsymbol{\mu}_1 - \boldsymbol{\mu}_2)\mathbf{x} + \frac{1}{2}(\boldsymbol{\mu}_2^T \Sigma^{-1} \boldsymbol{\mu}_2 - \boldsymbol{\mu}_1^T \Sigma^{-1} \boldsymbol{\mu}_1) + \log \frac{p(C_2)}{p(C_1)} = 0$$

Simple case: $\Sigma = \lambda \mathbf{I}$ (that is, $\sigma_{ii} = \lambda$ for i = 1, ..., d). In this case, the discriminant function is

$$2(\boldsymbol{\mu}_2 - \boldsymbol{\mu}_1)\mathbf{x} + \|\boldsymbol{\mu}_1\|^2 - \|\boldsymbol{\mu}_2\|^2 + 2\lambda \log \frac{p(C_2)}{p(C_1)} = 0$$

a.a. 2021-2022 15/32

Multiple classes

In this case, we refer to the softmax function:

$$p(C_k|\mathbf{x}) = s(a_k(\mathbf{x}))$$

where $a_k(\mathbf{x}) = \log(p(\mathbf{x}|C_k)p(C_k))$.

By the above considerations, it easily turns out that

$$a_k(\mathbf{x}) = \frac{1}{2} \left(\boldsymbol{\mu}_k^T \boldsymbol{\Sigma}^{-1} \mathbf{x} - \boldsymbol{\mu}_k^T \boldsymbol{\Sigma}^{-1} \boldsymbol{\mu}_k \right) + \log p(C_k) - \frac{d}{2} \log(2\pi) - \frac{1}{2} \log |\boldsymbol{\Sigma}| = \mathbf{w}_k^T \mathbf{x} + w_{0k}$$

Again, $p(C_k|\mathbf{x}) = \sigma(\mathbf{w}^T\mathbf{x} + w_0)$ is computed by applying a non-linear function to a linear combination of the features (generalized linear model)

a.a. 2021-2022 16/32

Multiple classes

Decision boundaries corresponding to the case when there are two classes C_j , C_k such that the corresponding posterior probabilities are equal, and larger than the probability of any other class. That is,

$$p(C_k|\mathbf{x}) = p(C_j|\mathbf{x})$$
 $p(C_i|\mathbf{x}) < p(C_k|\mathbf{x})$ $i \neq j, k$

hence

$$e^{a_k(\mathbf{x})} = e^{a_j(\mathbf{x})}$$
 $e^{a_i(\mathbf{x})} < e^{a^k(\mathbf{x})}$ $i \neq j, k$

that is,

$$a_k(\mathbf{x}) = a_j(\mathbf{x})$$
 $a_i(\mathbf{x}) < a^k(\mathbf{x})$ $i \neq j, k$

As shown, this implies that boundaries are linear.

a.a. 2021-2022 17/32

General covariance matrices, binary case

The class conditional distributions $p(\mathbf{x}|C_k)$ are gaussians with different covariance matrices

$$a(\mathbf{x}) = \log \frac{p(\mathbf{x}|C_1)p(C_1)}{p(\mathbf{x}|C_2)p(C_2)}$$

$$= \log \frac{exp\left(-\frac{1}{2}(\mathbf{x} - \boldsymbol{\mu}_1)^T \Sigma_1^{-1}(\mathbf{x} - \boldsymbol{\mu}_1)\right)}{exp\left(-\frac{1}{2}(\mathbf{x} - \boldsymbol{\mu}_2)^T \Sigma_2^{-1}(\mathbf{x} - \boldsymbol{\mu}_2)\right)} + \frac{1}{2}\log \frac{|\Sigma_2|}{|\Sigma_1|} + \log \frac{p(C_1)}{p(C_2)}$$

$$= \frac{1}{2}\left((\mathbf{x} - \boldsymbol{\mu}_2)^T \Sigma_2^{-1}(\mathbf{x} - \boldsymbol{\mu}_2) - (\mathbf{x} - \boldsymbol{\mu}_1)^T \Sigma_1^{-1}(\mathbf{x} - \boldsymbol{\mu}_1)\right) + \frac{1}{2}\log \frac{|\Sigma_2|}{|\Sigma_1|} + \log \frac{p(C_1)}{p(C_2)}$$

a.a. 2021-2022 18/32

General covariance matrices, binary case

By applying the same considerations, the decision boundary turns out to be

$$((\mathbf{x} - \boldsymbol{\mu}_2)^T \Sigma_2^{-1} (\mathbf{x} - \boldsymbol{\mu}_2) - (\mathbf{x} - \boldsymbol{\mu}_1)^T \Sigma_1^{-1} (\mathbf{x} - \boldsymbol{\mu}_1)) + \log \frac{|\Sigma_2|}{|\Sigma_1|} + 2 \log \frac{p(C_1)}{p(C_2)} = 0$$

Classes are separated by a (at most) quadratic surface.

a.a. 2021-2022 19/32

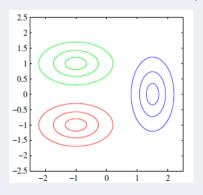

General covariance, multiple classe

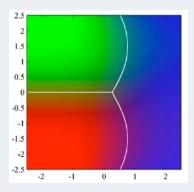

It can be proved that boundary surfaces are at most quadratic.

Example

Left: 3 classes, modeled by gaussians with different covariance matrices.

Right: posterior distribution of classes, with boundary surfaces.

a.a. 2021-2022 20 / 32

The class conditional distributions $p(\mathbf{x}|C_k)$ can be derived from the training set by maximum likelihood estimation.

For the sake of simplicity, assume K = 2 and both classes share the same Σ .

It is then necessary to estimate μ_1, μ_2, Σ , and $\pi = p(C_1)$ (clearly, $p(C_2) = 1 - \pi$).

a.a. 2021-2022 21/32

Training set \mathcal{T} : includes n elements (\mathbf{x}_i, t_i) , with

$$t_i = \begin{cases} 0 & \text{se } \mathbf{x}_i \in C_2 \\ 1 & \text{se } \mathbf{x}_i \in C_1 \end{cases}$$

If
$$\mathbf{x} \in C_1$$
, then $p(\mathbf{x}, C_1) = p(\mathbf{x}|C_1)p(C_1) = \pi \cdot N(\mathbf{x}|\boldsymbol{\mu}_1, \Sigma)$

If
$$\mathbf{x} \in C_2$$
, $p(\mathbf{x}, C_2) = p(\mathbf{x}|C_2)p(C_2) = (1 - \pi) \cdot N(\mathbf{x}|\boldsymbol{\mu}_2, \Sigma)$

The likelihood of the training set \mathcal{T} is

$$L(\pi, \boldsymbol{\mu}_1, \boldsymbol{\mu}_2, \boldsymbol{\Sigma} | \mathcal{T}) = \prod_{i=1}^n (\pi \cdot N(\mathbf{x}_i | \boldsymbol{\mu}_1, \boldsymbol{\Sigma}))^{t_i} ((1-\pi) \cdot N(\mathbf{x}_i | \boldsymbol{\mu}_2, \boldsymbol{\Sigma}))^{1-t_i}$$

a.a. 2021-2022 22/3

The corresponding log likelihood is

$$l(\pi, \boldsymbol{\mu}_1, \boldsymbol{\mu}_2, \boldsymbol{\Sigma} | \mathcal{T}) = \sum_{i=1}^n \left(t_i \log \pi + t_i \log(N(\mathbf{x}_i | \boldsymbol{\mu}_1, \boldsymbol{\Sigma})) \right) +$$

$$+ \sum_{i=1}^n \left((1 - t_i) \log(1 - \pi) + (1 - t_i) \log(N(\mathbf{x}_i | \boldsymbol{\mu}_2, \boldsymbol{\Sigma})) \right)$$

Its derivative wrt π is

$$\frac{\partial l}{\partial \pi} = \frac{\partial}{\partial \pi} \sum_{i=1}^{n} (t_i \log \pi + (1 - t_i) \log (1 - \pi)) = \sum_{i=1}^{n} \left(\frac{t_i}{\pi} - \frac{(1 - t_i)}{1 - \pi} \right) = \frac{n_1}{\pi} - \frac{n_2}{1 - \pi}$$

which is equal to 0 for

$$\pi = \frac{n_1}{n}$$

a.a. 2021-2022 23/32

The maximum wrt μ_1 (and μ_2) is obtained by computing the gradient

$$\frac{\partial l}{\partial \boldsymbol{\mu}_1} = \frac{\partial}{\partial \boldsymbol{\mu}_1} \sum_{i=1}^n t_i \log(N(\mathbf{x}_i | \boldsymbol{\mu}_1, \boldsymbol{\Sigma})) = \dots = \boldsymbol{\Sigma}^{-1} \sum_{i=1}^n t_i (\mathbf{x}_i - \boldsymbol{\mu}_1)$$

As a consequence, we have $\frac{\partial l}{\partial \mu_1} = 0$ for

$$\sum_{i=1}^n t_i \mathbf{x}_i = \sum_{i=1}^n t_i \boldsymbol{\mu}_1$$

hence, for

$$\mu_1 = \frac{1}{n_1} \sum_{\mathbf{x}_i \in C_1} \mathbf{x}_i$$

24 / 32

Similarly,
$$\frac{\partial l}{\partial \pmb{\mu}_2} = 0$$
 for

$$\boldsymbol{\mu}_2 = \frac{1}{n_2} \sum_{\mathbf{x}_i \in C_2} \mathbf{x}_i$$

Maximizing the log-likelihood wrt Σ provides

$$\Sigma = \frac{n_1}{n} \mathbf{S}_1 + \frac{n_2}{n} \mathbf{S}_2$$

where

$$\mathbf{S}_1 = \frac{1}{n_1} \sum_{\mathbf{x}_i \in C_1} (\mathbf{x}_i - \boldsymbol{\mu}_1) (\mathbf{x}_i - \boldsymbol{\mu}_1)^T$$

$$\mathbf{S}_2 = \frac{1}{n_2} \sum_{\mathbf{x}_i \in C_2} (\mathbf{x}_i - \boldsymbol{\mu}_2) (\mathbf{x}_i - \boldsymbol{\mu}_2)^T$$

and let

$$\mathbf{S} = \frac{n_1}{n} \mathbf{S}_1 + \frac{n_2}{n} \mathbf{S}_2$$

a.a. 2021-2022 26/32

GDA: discrete features

- In the case of d discrete (for example, binary) features we may apply the Naive Bayes hypothesis (independence of features, given the class)
- \odot Then, we may assume that, for any class C_k , the value of the *i*-th feature is sampled from a Bernoulli distribution of parameter p_{ki} ; by the conditional independence hypothesis, it results into

$$p(\mathbf{x}|C_k) = \prod_{i=1}^d p_{ki}^{x_i} (1 - p_{ki})^{1 - x_i}$$

where $p_{ki} = p(x_i = 1|C_k)$ could be estimated by ML, as in the case of language models

 \odot Functions $a_k(\mathbf{x})$ can then be defined as:

$$a_k(\mathbf{x}) = \log(p(\mathbf{x}|C_k)p(C_k)) = \sum_{i=1}^{D} (x_i \log p_{ki} + (1 - x_i)\log(1 - p_{ki})) + \log p(C_k)$$

These are still linear functions on \mathbf{x} .

 \odot The same considerations can be done in the case of non binary features, where, for any class C_k , we may assume the value of the *i*-th feature is sampled from a distribution on a suitable domain (e.g. Poisson in the case of count data)

a.a. 2021-2022 27 /

Generative models and the exponential family

The property that $p(C_k|\mathbf{x})$ is a generalized linear model with sigmoid (for the binary case) and softmax (for the multiclass case) activation function holds more in general than assuming a gaussian or bernoulli class conditional distribution $p(\mathbf{x}|C_k)$.

a.a. 2021-2022 28/32

Generative models and the exponential family

Indeed, let the class conditional probability wrt C_k belong to the exponential family, that is it may be written in the general form

$$p(\mathbf{x}|C_k) = \frac{1}{s}g(\boldsymbol{\theta}_k)f\left(\frac{\mathbf{x}}{s}\right)e^{\frac{1}{s}\boldsymbol{\theta}_k^T\mathbf{u}(\mathbf{x})} = \exp\left(\frac{1}{s}\left(\boldsymbol{\theta}_k^T\mathbf{u}(\mathbf{x}) + A(\boldsymbol{\theta}_k, s)\right) + C\left(\frac{\mathbf{x}}{s}\right)\right)$$

Here,

- 1. $\theta_k = (\theta_{k1}, \dots, \theta_{km})$ is an *m*-dimensional array (for a give, suitable, *m*) denoted as the *natural parameter*
- 2. **u** is a function mapping **x** to an *m*-dimensional array $\mathbf{u}(\mathbf{x}) = (\mathbf{u}(\mathbf{x})_1, \dots, \mathbf{u}(\mathbf{x})_m)$
- 3. s is a dispersion parameter
- 4. $g(\theta_k)$ normalizes the function values so that $\int p(\mathbf{x}|C_k)d\mathbf{x} = 1$, hence $g(\theta_k) = \frac{s}{\int f(\frac{\mathbf{x}}{s})e^{\frac{1}{s}\theta_k^T\mathbf{u}(\mathbf{x})d\mathbf{x}}}$; its inverse $\frac{s}{g(\theta_k)}$ is denoted as the *partition function*
- 5. clearly, $A(\theta_k, s) = \log \frac{g(\theta_k)}{s}$ and $C(\frac{\mathbf{x}}{s}) = \log f(\frac{\mathbf{x}}{s})$

a.a. 2021-2022 29/3

Exponential family

Let us consider the gaussian distribution. The distribution belongs to the exponential family since

$$p(x|\mu,\sigma) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right)$$
$$= \exp\left(-\frac{(x-\mu)^2}{2\sigma^2} - \log\left(\sqrt{2\pi}\sigma\right)\right)$$
$$= \exp\left(-\frac{x^2}{2\sigma^2} + x\frac{\mu}{\sigma^2} - \frac{\mu^2}{2\sigma^2} - \frac{1}{2}\log\left(2\pi\sigma^2\right)\right)$$

which fits the exponential family structure assuming $\boldsymbol{\theta} = (\frac{\mu}{\sigma^2}, -\frac{1}{\sigma^2}), \mathbf{u}(x) = (x, \frac{x^2}{2}), s = 1,$

$$A(\boldsymbol{\theta}, s) = -\frac{\mu^2}{2\sigma^2} - \log \sigma, C\left(\frac{\mathbf{x}}{s}\right) = -\frac{1}{2}\log(2\pi)$$

a.a. 2021-2022 30/32

Exponential family

Let us consider the bernoulli distribution $p(x|\pi) = \pi^x (1-\pi)^{1-x}$. The distribution belongs to the exponential family since

$$p(x|\pi) = \pi^{x} (1 - \pi)^{1 - x}$$

$$= \exp(x \log \pi + (1 - x) \log(1 - \pi)) = \exp\left(x \log \frac{\pi}{1 - \pi} + \log(1 - \pi)\right)$$

which fits the exponential family structure assuming $\theta = \log \frac{\pi}{1-\pi}$, u(x) = x, s = 1, $A(\theta, s) = \log(1-\pi)$, $C\left(\frac{\mathbf{x}}{s}\right) = 0$

a.a. 2021-2022 31/

Generative models and the exponential family

In the case of binary classification, we check that $a(\mathbf{x})$ is a linear function

$$a(\mathbf{x}) = \log \frac{p(\mathbf{x}|\boldsymbol{\theta}_1)p(\boldsymbol{\theta}_1)}{p(\mathbf{x}|\boldsymbol{\theta}_2)p(\boldsymbol{\theta}_2)} = \log \frac{g(\boldsymbol{\theta}_1)e^{\frac{1}{s}\boldsymbol{\theta}_1^T\mathbf{u}(\mathbf{x})}p(\boldsymbol{\theta}_1)}{g(\boldsymbol{\theta}_2)e^{\frac{1}{s}\boldsymbol{\theta}_2^T\mathbf{u}(\mathbf{x})}p(\boldsymbol{\theta}_2)}$$
$$= (\boldsymbol{\theta}_1 - \boldsymbol{\theta}_2)^T \mathbf{x} + \log g(\boldsymbol{\theta}_1) - \log g(\boldsymbol{\theta}_2) + \log p(\boldsymbol{\theta}_1) - \log p(\boldsymbol{\theta}_2)$$

Similarly, for multiclass classification, we may easily derive that

$$a_k(\mathbf{x}) = \boldsymbol{\theta}_k^T \mathbf{x} + \log g(\boldsymbol{\theta}_k) + p(\boldsymbol{\theta}_k)$$

for all k.

a.a. 2021-2022 32/32
