Probabilistic classification - discriminative models

Corso di Laurea Magistrale in Informatica

Università di Roma Tor Vergata

Prof. Giorgio Gambosi

a.a. 2021-2022

Generalized linear models

In the cases considered above, the posterior class distributions $p(C_k|\mathbf{x})$ are sigmoidal or softmax with argument given by a linear combination of features in \mathbf{x} , i.e., they are a instances of generalized linear models

A generalized linear model (GLM) is a function

$$y(\mathbf{x}) = f(\mathbf{w}^T \mathbf{x} + w_0)$$

where f (usually called the *response function*) is in general a non linear function.

Each iso-surface of $y(\mathbf{x})$, such that by definition $y(\mathbf{x}) = c$ (for some constant c), is such that

$$f(\mathbf{w}^T\mathbf{x} + w_0) = c$$

and

$$\mathbf{w}^T\mathbf{x} + w_0 = f^{-1}(y) = c'$$

(c' constant).

Hence, iso-surfaces of a GLM are hyper-planes, thus implying that boundaries are hyperplanes themselves.

a.a. 2021-2022 2/38

Exponential families and GLM

Let us assume we wish to predict a random variable y as a function of a different set of random variables x. By definition, a prediction model for this task is a GLM if the following hypotheses hold:

1. the conditional distribution of y given \mathbf{x} , $p(y|\mathbf{x})$ belongs to the exponential family: that is, we may write it as

$$p(y|\mathbf{x}) = \frac{1}{s}g(\boldsymbol{\theta}(\mathbf{x}))f\left(\frac{y}{s}\right)e^{\frac{1}{s}\boldsymbol{\theta}(\mathbf{x})^T\mathbf{u}(y)}$$

for suitable g, θ, \mathbf{u}

- 2. for any **x**, we wish to predict the expected value of $\mathbf{u}(y)$ given **x**, that is $E[\mathbf{u}(y)|\mathbf{x}]$
- 3. $\theta(\mathbf{x})$ (the natural parameter) is a linear combination of the features, $\theta(\mathbf{x}) = \mathbf{w}^T \overline{\mathbf{x}}$

a.a. 2021-2022 3/38

GLM and normal distribution

1. $y \in \mathbb{R}$, and $p(y|\mathbf{x}) = \frac{1}{\sqrt{2\pi}\sigma}e^{-\frac{(y-\mu(\mathbf{x}))^2}{2\sigma^2}}$ is a normal distribution with mean $\mu(\mathbf{x})$ and constant variance σ^2 : it is easy to verify that

$$\boldsymbol{\theta}(\mathbf{x}) = \begin{pmatrix} \theta_1(\mathbf{x}) \\ \theta_2 \end{pmatrix} = \begin{pmatrix} \mu(\mathbf{x})/\sigma^2 \\ -1/2\sigma^2 \end{pmatrix}$$

and $\mathbf{u}(y) = y$

2. we wish to predict the value of $E[\mathbf{u}(y)|\mathbf{x}]$ as $y(\mathbf{x}) = E[y|\mathbf{x}]$, then

$$y(\mathbf{x}) = \mu(\mathbf{x}) = \sigma^2 \theta_1(\mathbf{x})$$

3. we assume there exists \mathbf{w} such that $\theta_1(\mathbf{x}) = \mathbf{w}_1^T \overline{\mathbf{x}}$

Then, a linear regression results

$$y(\mathbf{x}) = \mathbf{w}_1^T \overline{\mathbf{x}}$$

a.a. 2021-2022 4/38

GLM and Bernoulli distribution

1. $y \in \{0, 1\}$, and $p(y|\mathbf{x}) = \pi(\mathbf{x})^y (1 - \pi(\mathbf{x}))^{1-y}$ is a Bernoulli distribution with parameter $\pi(\mathbf{x})$: then, the natural parameter $\theta(\mathbf{x})$ is

$$\theta(\mathbf{x}) = \log \frac{\pi(\mathbf{x})}{1 - \pi(\mathbf{x})}$$

and $\mathbf{u}(y) = y$

2. we wish to predict the value of $E[\mathbf{u}(y)|\mathbf{x}]$ as $y(\mathbf{x}) = E[y|\mathbf{x}] = p(y=1|\mathbf{x})$, then

$$p(y = 1|\mathbf{x}) = \pi(\mathbf{x}) = \frac{1}{1 + e^{-\theta(\mathbf{x})}}$$

3. we assume there exists **w** such that $\theta(\mathbf{x}) = \mathbf{w}^T \overline{\mathbf{x}}$

Then, a logistic regression derives

$$y(\mathbf{x}) = \frac{1}{1 + e^{-\mathbf{w}^T \overline{\mathbf{x}}}}$$

a.a. 2021-2022 5/38

GLM and categorical distribution

1. $y \in \{1, ..., K\}$, and $p(y|\mathbf{x}) = \prod_{i=1}^{K} \pi_i(\mathbf{x})^{y_i}$ (where $y_i = 1$ if y = i and y = 0 otherwise) is a categorical distribution with probabilities $\pi_1(\mathbf{x}), ..., \pi_K(\mathbf{x})$ (where $\sum_{i=1}^{K} \pi_i(\mathbf{x}) = 1$): the natural parameter is then $\boldsymbol{\theta}(\mathbf{x}) = (\theta_1(\mathbf{x}), ..., \theta_K(\mathbf{x}))^T$, with

$$\theta_i(\mathbf{x}) = \log \frac{\pi_i(\mathbf{x})}{\pi_K(\mathbf{x})} = \log \frac{\pi_i(\mathbf{x})}{1 - \sum_{j=1}^{K-1} \pi_j(\mathbf{x})}$$

and $\mathbf{u}(y) = (y_1, \dots, y_K)^T$ is the 1-to-K representation of y

2. we wish to predict the expectations $y_i(\mathbf{x}) = E[u_i(y)|\mathbf{x}] = p(y=i|\mathbf{x})$ as

$$p(y = i|\mathbf{x}) = E[u_i(y)|\mathbf{x}] = \pi_i(\mathbf{x}) = \pi_K(\mathbf{x})e^{\theta_i(\mathbf{x})}$$

Since $1 = \sum_{i=1}^K \pi_i(\mathbf{x}) = \pi_K(\mathbf{x}) \sum_{i=1}^K e^{\theta_i(\mathbf{x})}$, it derives

$$\pi_K(\mathbf{x}) = \frac{1}{\sum_{i=1}^K e^{\theta_i(\mathbf{x})}}$$
 and $\pi_i(\mathbf{x}) = \frac{e^{\theta_i(\mathbf{x})}}{\sum_{i=1}^K e^{\theta_i(\mathbf{x})}}$

3. we assume there exist $\mathbf{w}_1, \dots, \mathbf{w}_K$ such that $\theta_i(\mathbf{x}) = \mathbf{w}_i^T \overline{\mathbf{x}}$

a.a. 2021-2022 6/

GLM and categorical distribution

Then, a softmax regression results, with

$$y_i(\mathbf{x}) = \frac{e^{\mathbf{w}_i^T \overline{\mathbf{x}}}}{\sum_{j=1}^K e^{\mathbf{w}_j^T \overline{\mathbf{x}}}} \quad \text{if } i \neq K$$
$$y_K(\mathbf{x}) = \frac{1}{\sum_{j=1}^K e^{\mathbf{w}_j^T \overline{\mathbf{x}}}}$$

GLM and additional regressions

Other regression types can be defined by considering different models for $p(y|\mathbf{x})$. For example,

1. Assume $y \in \{0, ..., \}$ is a non negative integer (for example we are interested to count data), and $p(y|\mathbf{x}) = \frac{\lambda(\mathbf{x})^y}{y!} e^{-\lambda(\mathbf{x})}$ is a Poisson distribution with parameter $\lambda(\mathbf{x})$: then, the natural parameter $\theta(\mathbf{x})$ is

$$\theta(\mathbf{x}) = \log \lambda(\mathbf{x})$$

and $\mathbf{u}(y) = y$

2. we wish to predict the value of $E[\mathbf{u}(y)|\mathbf{x}]$ as $y(\mathbf{x}) = E[y|\mathbf{x}]$, then

$$y(\mathbf{x}) = \lambda(\mathbf{x}) = e^{\theta(\mathbf{x})}$$

3. we assume there exists **w** such that $\theta(\mathbf{x}) = \mathbf{w}^T \overline{\mathbf{x}}$

Then, a Poisson regression derives

$$y(\mathbf{x}) = e^{\mathbf{w}^T \overline{\mathbf{x}}}$$

a.a. 2021-2022 8/38

GLM and additional regressions

1. Assume $y \in [0, \infty)$ is a non negative real (for example we are interested to time intervals), and $p(y|\mathbf{x}) = \lambda(\mathbf{x})e^{-\lambda(\mathbf{x})y}$ is an exponential distribution with parameter $\lambda(\mathbf{x})$: then, the natural parameter $\theta(\mathbf{x})$ is

$$\theta(\mathbf{x}) = -\lambda(\mathbf{x})$$

and $\mathbf{u}(y) = y$

2. we wish to predict the value of $E[\mathbf{u}(y)|\mathbf{x}]$ as $y(\mathbf{x}) = E[y|\mathbf{x}]$, then

$$y(\mathbf{x}) = \frac{1}{\lambda(\mathbf{x})} = -\frac{1}{\theta(\mathbf{x})}$$

3. we assume there exists **w** such that $\theta(\mathbf{x}) = \mathbf{w}^T \overline{\mathbf{x}}$

Then, an exponential regression derives

$$y(\mathbf{x}) = -\frac{1}{\mathbf{w}^T \overline{\mathbf{x}}}$$

a.a. 2021-2022 9/38

Discriminative approach

We could directly assume that $p(C_k|\mathbf{x})$ is a GLM and derive its coefficients (for example through ML estimation).

Comparison wrt the generative approach:

- \odot Less information derived (we do not know $p(\mathbf{x}|C_k)$, thus we are not able to generate new data)
- Simpler method, usually a smaller set of parameters to be derived
- ⊚ Better predictions, if the assumptions done with respect to $p(\mathbf{x}|C_k)$ are poor.

a.a. 2021-2022 10/38

Logistic regression

$$p(C_1|\mathbf{x}) = \sigma(\mathbf{w}^T\mathbf{x}) = \frac{1}{1 + e^{-\mathbf{w}^T\overline{\mathbf{x}}}}$$

where base functions could also be applied.

The model is equivalent, for the binary classification case, to linear regression for the regression case.

a.a. 2021-2022 11/38

Degrees of freedom

- In the case of d features, logistic regression requires d+1 coefficients w_0, \dots, w_d to be derived from a training set
- A generative approach with gaussian distributions requires:
 - 2d coefficients for the means μ_1, μ_2 ,
 - for each covariance matrix

$$\sum_{i=1}^{d} i = d(d+1)/2$$
 coefficients

- one prior cla probability $p(C_1)$
- \odot As a total, it results into d(d+1) + 2d + 1 = d(d+3) + 1 coefficients (if a unique covariance matrix is assumed d(d + 1)/2 + 2d + 1 = d(d + 5)/2 + 1 coefficients)

12 / 38

Let us assume that targets of elements of the training set can be conditionally (with respect to model coefficients) modeled through a Bernoulli distribution. That is, assume

$$p(t_i|\mathbf{x}_i,\mathbf{w}) = p_i^{t_i}(1-p_i)^{1-t_i}$$

where $p_i = p(C_1|\mathbf{x}_i) = \sigma(\mathbf{w}^T\mathbf{x}_i)$.

Then, the likelihood of the training set targets \mathbf{t} given \mathbf{X} is

$$p(\mathbf{t}|\mathbf{X}, \mathbf{w}) = L(\mathbf{w}|\mathbf{X}, \mathbf{t}) = \prod_{i=1}^{n} p(t_i|\mathbf{x}_i, \mathbf{w}) = \prod_{i=1}^{n} p_i^{t_i} (1 - p_i)^{1 - t_i}$$

and the log-likelihood is

$$l(\mathbf{w}|\mathbf{X}, \mathbf{t}) = \log L(\mathbf{w}|\mathbf{X}, \mathbf{t}) = \sum_{i=1}^{n} (t_i \log p_i + (1 - t_i) \log(1 - p_i))$$

a.a. 2021-2022 13/38

It results

$$\frac{\partial l(\mathbf{w}|\mathbf{X},\mathbf{t})}{\partial \mathbf{w}} = \sum_{i=1}^{n} (t_i - p_i) \overline{\mathbf{x}}_i = \sum_{i=1}^{n} (t_i - \sigma(\mathbf{w}^T \overline{\mathbf{x}}_i)) \overline{\mathbf{x}}_i$$

To maximize the likelihood, we could apply a gradient ascent algorithm, where at each iteration the following update of the currently estimated \mathbf{w} is performed

$$\mathbf{w}^{(j+1)} = \mathbf{w}^{(j)} + \alpha \frac{\partial l(\mathbf{w}|\mathbf{X}, \mathbf{t})}{\partial \mathbf{w}}|_{\mathbf{w}^{(j)}}$$
$$= \mathbf{w}^{(j)} + \alpha \sum_{i=1}^{n} (t_i - \sigma((\mathbf{w}^{(j)})^T \overline{\mathbf{x}}_i)) \overline{\mathbf{x}}_i$$
$$= \mathbf{w}^{(j)} + \alpha \sum_{i=1}^{n} (t_i - y(\mathbf{x}_i)) \overline{\mathbf{x}}_i$$

a.a. 2021-2022 15/38

As a possible alternative, at each iteration only one coefficient in ${\bf w}$ is updated

$$w_k^{(j+1)} = w_k^{(j)} + \alpha \frac{\partial l(\mathbf{w}|\mathbf{X}, \mathbf{t})}{\partial w_k} \Big|_{\mathbf{w}^{(j)}}$$

$$= w_k^{(j+1)} + \alpha \sum_{i=1}^n (t_i - \sigma((\mathbf{w}^{(j)})^T \overline{\mathbf{x}}_i)) x_{ik}$$

$$= w_k^{(j+1)} + \alpha \sum_{i=1}^n (t_i - y(\mathbf{x}_i)) x_{ik}$$

a.a. 2021-2022 16/38

Newton-Raphson method

- \odot Maximization of $l(\mathbf{w}|\mathbf{X}, \mathbf{t})$ through the well-known Newton-Raphson algorithm to compute the roots of a given function
- ⊚ Given $f: \mathbb{R} \mapsto \mathbb{R}$, the algorithm finds $z \in \mathbb{R}$ such that f(z) = 0 through a sequence of iterations, starting from an initial value z_0 and performing the following update

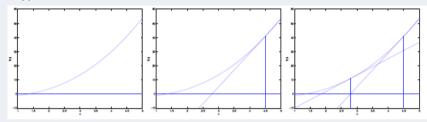

$$z_{i+1} = z_i - \frac{f(z_i)}{f'(z_i)}$$

 \odot At each iteration, the algorithm approximates f by a line tangent to f in $(z_i, f(z_i))$, and defines z_{i+1} as the value where the line intersects the x axis

a.a. 2021-2022 17/38

Newton-Raphson method

Example of application of the method

 Newton-Raphson method can be also applied to compute maximum and minimum points for a function by finding zeros of the first derivative: this corresponds to applying the following update

$$z_{i+1} = z_i - \frac{f'(z_i)}{f''(z_i)}$$

a.a. 2021-2022 18/38

Newton-Raphson and multivariate functions

- To apply Newton-Raphson to logistic regression we have to extend it to the case of a vector variable, since the maximization has to be performed with respect to the vector w of coefficients
- In a multivariate framework, the first derivative is substituted by the gradient $\frac{\partial}{\partial \mathbf{w}}$, while the second derivative corresponds to the Hessian matrix H. defined as follows

$$\mathbf{H}_{ij}(f) = \frac{\partial^2 f}{\partial w_i \partial w_j}$$

The update operation turns out to be

$$\mathbf{w}^{(i+1)} = \mathbf{w}^{(i)} - (\mathbf{H}(f)|_{\mathbf{w}^{(i)}})^{-1} \frac{\partial f}{\partial \mathbf{w}}|_{\mathbf{w}_{(i)}}$$

19 / 38

Newton-Raphson and linear regression

In the case of linear regression, the error function to be minimized is

$$E(\mathbf{w}) = \frac{1}{2} \sum_{i=1}^{n} (y_i - t_i)^2 = \frac{1}{2} \sum_{i=1}^{n} (\mathbf{w}^T \overline{\mathbf{x}}_i - t_i)^2$$

Then,

$$\frac{\partial E}{\partial \mathbf{w}} = \sum_{i=1}^{n} (y_i - t_i) \overline{\mathbf{x}}_i = \overline{\mathbf{x}}^T \overline{\mathbf{x}} \mathbf{w} - \overline{\mathbf{x}}^T \mathbf{t}$$

$$\mathbf{H} = \frac{\partial}{\partial \mathbf{w}} \frac{\partial E}{\partial \mathbf{w}} = \sum_{i=1}^{n} \overline{\mathbf{x}}_{i} \overline{\mathbf{x}}_{i}^{T} = \overline{\mathbf{x}}^{T} \overline{\mathbf{x}}$$

At each iteration, the update is

$$\mathbf{w}^{(i+1)} = \mathbf{w}^{(i)} - (\overline{\mathbf{x}}^T \overline{\mathbf{x}})^{-1} (\overline{\mathbf{x}}^T \overline{\mathbf{x}} \mathbf{w}^{(i)} - \overline{\mathbf{x}}^T \mathbf{t}) = (\overline{\mathbf{x}}^T \overline{\mathbf{x}})^{-1} \overline{\mathbf{x}}^T \mathbf{t}$$

We get the well-known solution, which is obtained in a single iteration.

a.a. 2021-2022 20/38

Newton-Raphson and logistic regression

There, we have the cross entropy loss function

$$E(\mathbf{w}) = -l(\mathbf{w}|\mathbf{X}, \mathbf{t}) = -\sum_{i=1}^{n} (t_i \log y_i + (1 - t_i) \log(1 - y_i))$$

with $y_i = \sigma(a_i)$ and $a_i = w^T \overline{\mathbf{x}}_i$. Hence,

$$\frac{\partial E}{\partial \mathbf{w}} = -\frac{\partial l(\mathbf{w}|\mathbf{X}, \mathbf{t})}{\partial \mathbf{w}} = \sum_{i=1}^{n} (y_i - t_i) \overline{\mathbf{x}}_i = \overline{\mathbf{x}}^T (\mathbf{y} - \mathbf{t})$$

$$\mathbf{H} = \frac{\partial}{\partial \mathbf{w}} \frac{\partial E}{\partial \mathbf{w}} = \sum_{i=1}^{n} y_i (1 - y_i) \overline{\mathbf{x}}_i \overline{\mathbf{x}}_i^T = \overline{\mathbf{x}}^T \mathbf{Y} \overline{\mathbf{x}}$$

where

- \odot **y** is the vector of predictions $y_i = \sigma(a_i) = \sigma(\mathbf{w}^T \overline{\mathbf{x}}_i)$ for i = 1, ..., n
- \odot **Y** is a $n \times n$ diagonal matrix such that

$$Y_{ii} = y_i(1 - y_i)$$

a.a. 2021-2022 21/3

Newton-Raphson and logistic regression

In the case of logistic regression, the update is then

$$\mathbf{w}^{(i+1)} = \mathbf{w}^{(i)} - (\overline{\mathbf{x}}^T \mathbf{Y}^{(i)} \overline{\mathbf{x}})^{-1} \overline{\mathbf{x}}^T (\mathbf{y}^{(i)} - \mathbf{t})$$

where both \mathbf{y} and \mathbf{Y} are dependent from $\mathbf{w}^{(i)}$, hence from i. Then,

$$\mathbf{w}^{(i+1)} = (\overline{\mathbf{x}}^T \mathbf{Y}^{(i)} \overline{\mathbf{x}})^{-1} \overline{\mathbf{x}}^T \mathbf{Y}^{(i)} \mathbf{z}^{(i)}$$

where

$$\mathbf{z}^{(i)} = \mathbf{a}^{(i)} - \mathbf{Y}^{(i)}^{-1} (\mathbf{y}^{(i)} - \mathbf{t})$$

Clearly, $\mathbf{z}^{(i)}$ is a function of $\mathbf{w}^{(i)}$, hence of the step i.

a.a. 2021-2022 22/38

Iterated reweighted least squares

 Let us consider the weighted extension of the least squares cost function, denoted as weighted least squares cost function, defined as

$$\sum_{i=1}^{n} \psi_i(\mathbf{y}_i - t_i)^2 = \sum_{i=1}^{n} \psi_i(\mathbf{w}^T \overline{\mathbf{x}}_i - t_i)^2$$

for given weights ψ_1, \dots, ψ_n . Clearly, the least squares problems corresponds to the case $\psi_i = 1$ for $i = 1, \dots, n$

It can be proved that, for this problem, the optimum is

$$\mathbf{w} = (\overline{\mathbf{x}}^T \mathbf{\Psi} \overline{\mathbf{x}})^{-1} \overline{\mathbf{x}}^T \mathbf{\Psi} \mathbf{t}$$

where the weight matrix Ψ is a diagonal matrix with $\Psi_{ii} = \psi_i$

a.a. 2021-2022 23/38

Iterated reweighted least squares

Let us remind that, at each step of NR algorithm applied to logistic regression, the following update is performed

$$\mathbf{w}^{(i+1)} = (\overline{\mathbf{x}}^T \mathbf{Y}^{(i)} \overline{\mathbf{x}})^{-1} \overline{\mathbf{x}}^T \mathbf{Y}^{(i)} \mathbf{z}^{(i)}$$

- This corresponds to optimizing the weighted least squares cost function for feature matrix X, target vector $\tilde{\mathbf{t}} = \mathbf{z}^{(i)}$, and weights $\psi_k = v_k^{(i)} (1 - v_k^{(i)})$
- \odot The update of $\mathbf{w}^{(i)}$ performed at each iteration can then be computed by solving a new instance of the weighted least square problem, setting $\mathbf{w}^{(i+1)}$ to the solution obtained, and deriving the new values of $\Psi = \mathbf{V}^{(i+1)}$ and $\tilde{\mathbf{t}} = \mathbf{z}^{(i+1)}$

24 / 38

Logistic regression and GDA

- ® Observe that assuming $p(\mathbf{x}|C_1)$ are $p(\mathbf{x}|C_2)$ as multivariate normal distributions with same covariance matrix Σ results into a logistic $p(C_1|\mathbf{x})$.
- The opposite, however, is not true in general: in fact, GDA relies on stronger assumptions than logistic regression.
- The more the normality hypothesis of class conditional distributions with same covariance is verified, the more GDA will tend to provide the best models for $p(C_1|\mathbf{x})$

a.a. 2021-2022 25 / 38

Logistic regression and GDA

- Logistic regression relies on weaker assumptions than GDA: it is then less sensible from a limited correctness of such assumptions, thus resulting in a more robust technique
- © Since $p(C_i|\mathbf{x})$ is logistic under a wide set of hypotheses about $p(\mathbf{x}|C_i)$, it will usually provide better solutions (models) in all such cases, while GDA will provide poorer models as far as the normality hypotheses is less verified.

a.a. 2021-2022 26/38

Softmax regression

- \odot In order to extend the logistic regression approach to the case K > 2, let us consider the matrix $\mathbf{W} = (\mathbf{w}_1, \dots, \mathbf{w}_K)$ of model coefficients, of size $(d+1) \times K$, where \mathbf{w}_i is the d+1-dimensional vector of coefficients for class C_i .
- In this case, the likelihood is defined as

$$p(\mathbf{T}|\mathbf{X}, \mathbf{W}) = \prod_{i=1}^{n} \prod_{k=1}^{K} p(C_k|\mathbf{x}_i)^{t_{ik}} = \prod_{i=1}^{n} \prod_{k=1}^{K} \left(\frac{e^{\mathbf{W}_k^T \overline{\mathbf{x}}_i}}{\sum_{r=1}^{K} e^{\mathbf{W}_r^T \overline{\mathbf{x}}_i}} \right)^{t_{ik}}$$

where **X** is the usual matrix of features and **T** is the $n \times K$ matrix where row i is the 1-to-K coding of t_i . That is, if $\mathbf{x}_i \in C_k$ then $t_{ik} = 1$ and $t_{ir} = 0$ for $r \neq k$.

ML and softmax regression

The log-likelihood is then defined as

$$l(\mathbf{W}) = \sum_{i=1}^{n} \sum_{k=1}^{K} t_{ik} \log \left(\frac{e^{\mathbf{W}_{k}^{T} \overline{\mathbf{x}}_{i}}}{\sum_{r=1}^{K} e^{\mathbf{W}_{r}^{T} \overline{\mathbf{x}}_{i}}} \right)$$

And the gradient is defined as

$$\frac{\partial l(\mathbf{W})}{\partial \mathbf{W}} = \left(\frac{\partial l(\mathbf{W})}{\partial \mathbf{w}_1}, \dots, \frac{\partial l(\mathbf{W})}{\partial \mathbf{w}_K}\right)$$

28 / 38

ML and softmax regression

It is possible to show that

$$\frac{\partial l(\mathbf{W})}{\partial \mathbf{w}_j} = \sum_{i=1}^n (t_{ij} - y_{ij}) \overline{\mathbf{x}}_i$$

Observe that the gradient has the same structure than in the case of linear regression and logistic regression

29 / 38

Probit regression

- ⊚ In a GLM, $p(C_1|\mathbf{x}) = f(\mathbf{w}^T\overline{\mathbf{x}})$ where f is the activation function (a sigmoid in the case of logistic regression)
- In probit regression a stochastic threshold model is applied for classification, as follows:
 - Assume a probability distribution $\pi(\theta)$ is given, and let $\Pi(\theta)$ be the corresponding cumulative distribution: that is, $\Pi(z) = \pi(\theta < z)$
 - Let w be the model coefficients. In order to classify x, the linear combination $a_i = \mathbf{w}^T \overline{\mathbf{x}}$ is computed
 - By definition, $p(C_1|\mathbf{x}) = \Pi(\mathbf{w}^T\overline{\mathbf{x}})$: that is, $p(C_1|\mathbf{x})$ corresponds to the probability that a value sampled from $\pi(\theta)$ is less than $\mathbf{w}^T\overline{\mathbf{x}}$
- \odot That is, the activation function, i.e. the probability that **x** is classified in C_1 , is given by the cumulative function

$$f(a) = \int_{-\infty}^{\mathbf{w}^T \overline{\mathbf{x}}} \pi(\theta) d\theta$$

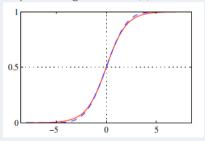

a.a. 2021-2022 30/38

Probit regression

 \odot A relevant case is the one of a gaussian $\pi(\theta)$ with zero mean and unitary variance, which results into a probit activation function

$$\Phi(a) = \int_{-\infty}^{a} \frac{1}{\sqrt{2\pi}} e^{-\frac{\theta^2}{2}} d\theta$$

 \odot observe that $\Phi(a)$ is monotonically increasing, with $0 < \Phi(a) < 1$

Usually, similar to logistic regression

a.a. 2021-2022 31/38

Bayesian logistic regression

- Used to overcome the overfitting problem by assuming a prior distribution
- The aim is to estimate the posterior class (predictive) distribution, that is the expectation of the model prediction wrt to the distribution of model coefficients,

$$p(C_1|\mathbf{x}, \mathbf{X}, \mathbf{t}) = \int p(C_1|\mathbf{x}, \mathbf{w}) p(\mathbf{w}|\mathbf{X}, \mathbf{t}) d\mathbf{w}$$
$$= \int \sigma(\mathbf{w}^T \overline{\mathbf{x}}) p(\mathbf{w}|\mathbf{X}, \mathbf{t}) d\mathbf{w}$$

 \odot we need some way to evaluate the posterior distribution of coefficients $p(\mathbf{w}|\mathbf{X},\mathbf{t})$ for any \mathbf{w}

a.a. 2021-2022 32/38

Posterior distribution of coefficients

By Bayes' rule,

$$p(\mathbf{w}|\mathbf{X}, \mathbf{t}) = \frac{p(\mathbf{t}|\mathbf{X}, \mathbf{w})p(\mathbf{w})}{p(\mathbf{t}|\mathbf{X})} = \frac{p(\mathbf{t}|\mathbf{X}, \mathbf{w})p(\mathbf{w})}{\int p(\mathbf{t}|\mathbf{X}, \mathbf{w}')p(\mathbf{w}')d\mathbf{w}'}$$

where the likelihood is $p(\mathbf{t}|\mathbf{X}, \mathbf{w}) = \prod_{i=1}^{n} p(t_i|\mathbf{x}_i, \mathbf{w})$, with

$$p(t_i|\mathbf{x}_i, \mathbf{w}) = \begin{cases} \sigma(\mathbf{w}^T \overline{\mathbf{x}}) & \text{if } t_i = 1\\ 1 - \sigma(\mathbf{w}^T \overline{\mathbf{x}}) & \text{if } t_i = 0 \end{cases}$$

a.a. 2021-2022 33/38

Posterior distribution of coefficients

That is.

$$p(\mathbf{t}|\mathbf{X}, \mathbf{w}) = \prod_{i=1}^{n} \sigma(\mathbf{w}^{T} \overline{\mathbf{x}})^{t_i} \left(1 - \sigma(\mathbf{w}^{T} \overline{\mathbf{x}})\right)^{1 - t_i}$$

and

$$p(\mathbf{w}|\mathbf{X},\mathbf{t}) = \frac{p(\mathbf{w}) \prod_{i=1}^{n} \sigma(\mathbf{w}^{T}\overline{\mathbf{x}})^{t_i} \left(1 - \sigma(\mathbf{w}^{T}\overline{\mathbf{x}})\right)^{1 - t_i}}{Z}$$

with the normalization factor

$$Z = \int p(\mathbf{w}) \prod_{i=1}^{n} \sigma(\mathbf{w}^{T} \overline{\mathbf{x}})^{t_i} \left(1 - \sigma(\mathbf{w}^{T} \overline{\mathbf{x}})\right)^{1 - t_i} d\mathbf{w}$$

34 / 38

Predictive distribution intractability

Z is hard to compute: we are only able to evaluate the numerator

$$g(\mathbf{w}; \mathbf{X}, \mathbf{t}) = p(\mathbf{w}) \prod_{i=1}^{n} \sigma(\mathbf{w}^{T} \overline{\mathbf{x}})^{t_i} \left(1 - \sigma(\mathbf{w}^{T} \overline{\mathbf{x}})\right)^{1 - t_i}$$

which is proportional to $p(\mathbf{w}|\mathbf{X},\mathbf{t})$ through an unknown proportionality coefficient.

Predictive distribution intractability

Possible options:

- 1. find a single value of \mathbf{w} which maximizes $p(\mathbf{w}|\mathbf{X}, \mathbf{t})$: this corresponds to the value which maximizes $g(\mathbf{w}; \mathbf{X}, \mathbf{t})$ (this is the usual MAP approach)
- 2. approximate $p(\mathbf{w}|\mathbf{X}, \mathbf{t})$ with some other probability density which can be treated analytically (*variational* approach)
- 3. sample from $p(\mathbf{w}|\mathbf{X}, \mathbf{t})$, knowing only $g(\mathbf{w}; \mathbf{X}, \mathbf{t})$ (*Montecarlo* approach)
